Consider the trinomial ( $x^2 - 3x - 10$ ). Your goal is to break up the number 10 into pairs of factors in such a way that when you add those two factors of 10, they have a difference of 3, which is the coefficient of the middle term.

### Tricks to Factoring Trinomials | Sciencing

Factoring a Quadratic Polynomial, Part 2. In this section, we're going to look at the "general" quadratic equation. In our first discussion of this kind of polynomial, we looked only at the case where the first or "leading" coefficient was one.

A difference in two perfect squares by definition states that there must be two terms, the sign between the two terms is a minus sign, and each of the two terms contain perfect squares. The answer after factoring the difference in two squares includes two binomials. One of the binomials contains the sum of two terms and the other contains the difference of two terms.

Trinomials: An expression with three terms added together.  $2x^2 + 6x - 8$  will serve as our lucky demonstrator. First, factor out the GCF. This will ALWAYS be your first step when factoring ANY expression.  $2(x^2 + 3x - 4)$  If you end up with a power of  $x$  greater than two after factoring out the GCF, move on to another step. List the integer factors of the constant.

$(a + b)(c + d) = ac + ad + bc + bd$  To multiply binomials, you need to distribute twice. Notice in the pattern above that first the  $a$  was distributed to everything in the 2<sup>nd</sup> parenthesis ( $c$  and  $d$ ). Then, the  $b$  was distributed to everything in the 2<sup>nd</sup> parenthesis ( $c$  and  $d$ ). One way to remember this is with the acronym FOIL
